DEVICE TEST

1, Explain behaviour of hub device

Hub works at Layer 1 only - it just repeats whatever it receives out to every other port, no MAC learning, no intelligence. All ports share one collision domain and one broadcast domain, so more devices means more collisions and slower network.

2, Explain behaviour of switch device

Switch works at Layer 2 - it learns the MAC address on each port and forwards frames only to the correct destination port instead of flooding everywhere, except for broadcast/unknown traffic. Each port is its own collision domain, which makes it far more efficient than a hub.

3, Explain behaviour of router device

Router works at Layer 3 - it connects different networks together using IP addressing, and uses a routing table to pick the best path to forward a packet. Routers also break up broadcast domains - broadcast traffic never crosses a router by default.
